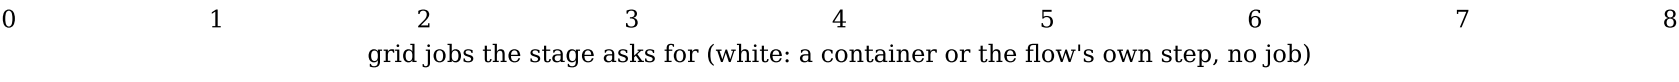
B The stages, in order, with the jobs each needs and the decision it informs

1 export (grid-cpu): the truth table and the PDM points exist and the three frame gaps are numbers (0 jobs only if the line-end export and morphoview reach the pinned copy before the two counted morphometry jobs are sent)

2 features with no network (grid-cpu): whether named measurements name as well as a latent at the feature level, under the exact rule and a classifier, and what K is; the within-column correlation that sets the naming bar

3 smoke of the heads (grid-cpu): the six heads run end to end and the CPU step time of each is measured (0 only if the head block joins phantom_smoke before its PREREG is frozen, else one CPU job of this evaluation's own flow kind)

4 screen (grid-gpu): greg's rule: every arm side by side, arm A at three seeds, 50 epochs on a fifth of the training persons, read on validation only, each trial an array task on its own card and a merge after; which arms train, calibrate and name at all, and their order

5 full run (grid-gpu): the primary endpoints per arm with intervals, from the kept arms at three seeds on the whole training part, the merge reading the test persons once for every trial


6 report (container): greg's decision against the bars
